University of Chicago, April 2nd, 2009

The many faces of biological robustness

Cancer and robustness

Hunt for fragility: weaknesses in tumour growth dynamics could yield new anti-cancer therapies.

Development and Robustness

How Does "Robust, Yet Fragile" Manifest Itself in the Example Systems? Biological organisms are highly robust to uncertainty in their environments and component parts yet can be catastrophically disabled by tiny perturbations to genes or the presence of microscopic pathogens or trace amounts of toxins that disrupt structural elements or regulatory control networks. The 777 is robust to

von Dassow's robustness

Redundancy and distribution of fragility: k robustness

Multiple knockout analysis of genetic robustness in the yeast metabolic network

David Deutscher¹, Isaac Meilijson², Martin Kupiec³ & Eytan Ruppin^{1,4}

Figure 3 Metabolic network robustness across different functional GO-Slim categories on rich medium, showing for each category the proportions of essential genes (dark), backed up genes (light), and genes not found to contribute in our analysis (white). Superimposed numbers indicate gene counts (for clarity, only counts of 3 or more are indicated). Only categories annotated with at least ten genes are included. The respective measurements in glucose minimal medium are very similar, except that many more of the genes involved in amino acid and derivative metabolism are essential (45/110).

Figure 5 Environmental specificity (ES) and propensity for gene loss (PGL) as a function of robustness level. Means \pm s.e.m. are shown for the ES (a) and PGL (b) measures at each k robustness level. The dashed lines are the least squares linear regression through the original data points. Owing to their small number and the uncertainty in their robustness level estimation, we do not consider genes with k robustness >9 , although the significant correlations found remain valid across k robustness thresholds from 5–12. The correlation between k robustness and PGL goes beyond the previously reported correlation between essentiality and evolutionary conservation^{21–24}, as it remains significant even when considering only nonessential genes ($R = 0.26$, $P = 5 \times 10^{-5}$, $N = 235$).

Prolegomena for a mathematical theory of biological robustness

- ▶ Robustness by dimension reduction : from von Dassow to Gromov
- ▶ Model reduction : a framework for studying robustness
- ▶ Multi-fold robustness : a lesson from the fly

Robustness by dimension compression

Chain of catalysed transformations

Transcription models

Gromov-Levy cube concentration

Objects in high-dimension look small in projection.

Gromov-Levy cube concentration

Objects in high-dimension look small in projection.

Levy theorem (cube concentration): $F(k_1, k_2, \dots, k_n)$ with F 1-Lipschitzian on $S^n(1)$ concentrates (roughly $\text{Var}(F) \sim 1/n$).

Gromov-Levy cube concentration

Objects in high-dimension look small in projection.

Levy theorem (cube concentration): $F(k_1, k_2, \dots, k_n)$ with F 1-Lipschitzian on $S^n(1)$ concentrates (roughly $\text{Var}(F) \sim 1/n$).

Examples : $\frac{1}{n} \sum_{i=1}^n x_i$, $\frac{1}{\sqrt{n}}$ -Lipschitzian on $S^n(\sqrt{n})$.

Gromov-Levy cube concentration

Objects in high-dimension look small in projection.

Min - max combinations

Von Dassow's robustness

von Dassow et al Nature 00

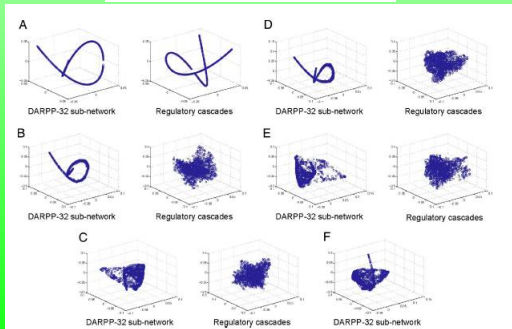

Hypothesis: robustness by dimension compression.

To prove this: a) dynamics is low dimensional (possible). b) there are only a few critical parameters (true). c) construct the coarse graining mapping (difficult).

DARPP-32 pathway: dynamics is low dimensional

Barbano et al., PNAS 2007.

Model reduction for Linear Networks of Chemical Reactions

All the reactions are of the type $A_i \rightarrow A_j$

Model reduction for Linear Networks of Chemical Reactions

All the reactions are of the type $A_i \rightarrow A_j$

Kinetic equation

$$\frac{dc_i}{dt} = k_{i0} + \sum_{j \geq 1} k_{ij} c_j - \left(\sum_{j \geq 0} k_{ji} \right) c_i,$$

Model reduction for Linear Networks of Chemical Reactions

All the reactions are of the type $A_i \rightarrow A_j$

Kinetic equation

$$\frac{dc_i}{dt} = k_{i0} + \sum_{j \geq 1} k_{ij} c_j - \left(\sum_{j \geq 0} k_{ji} \right) c_i,$$

separated constants

$$k_{l_1} \ll k_{l_2} \ll k_{l_3} \ll \dots, l = (i, j)$$

Model reduction for Linear Networks of Chemical Reactions

All the reactions are of the type $A_i \rightarrow A_j$

Kinetic equation

$$\frac{dc_i}{dt} = k_{i0} + \sum_{j \geq 1} k_{ij} c_j - \left(\sum_{j \geq 0} k_{ji} \right) c_i,$$

separated constants

$$k_{l_1} \ll k_{l_2} \ll k_{l_3} \ll \dots, l = (i, j)$$

Eigenvalues and eigenvectors specify dynamics of linear systems

$$c(t) = (I^0, c(0)) + \sum_{k=1}^{n-1} r^k (I^k, c(0)) \exp(-\lambda_k t)$$

Model reduction for Linear Networks of Chemical Reactions

All the reactions are of the type $A_i \rightarrow A_j$

Kinetic equation

$$\frac{dc_i}{dt} = k_{i0} + \sum_{j \geq 1} k_{ij} c_j - \left(\sum_{j \geq 0} k_{ji} \right) c_i,$$

separated constants

$$k_{l_1} \ll k_{l_2} \ll k_{l_3} \ll \dots, l = (i, j)$$

Eigenvalues and eigenvectors specify dynamics of linear systems

$$c(t) = (I^0, c(0)) + \sum_{k=1}^{n-1} r^k (I^k, c(0)) \exp(-\lambda_k t)$$

dominant subsystems: reduced models providing approximations to eigenvectors and eigenvalues.

Model reduction for Linear Networks of Chemical Reactions

All the reactions are of the type $A_i \rightarrow A_j$

Kinetic equation

$$c(t) = (I^0, c(0)) + \sum_{k=1}^{n-1} r^k (I^k, c(0)) \exp(-\lambda_k t)$$

dominant subsystems: reduced models providing approximations to eigenvectors and eigenvalues.

goal: Compute dominant subsystems for arbitrary reaction networks with well separated constants

Limitation theory for linear, hierarchical models: an example

Gorban and Radulescu Adv.Chem.Eng.08, Radulescu et al BMC Systems Biol. 08

A more complicated example: the prism

The prism is a model used in biophysics (Kurzynski Prog.Biophys.Mol.Biol. 98).

The full model

The auxiliary dynamical system

Glue cycles

The limiting constant is k_{32} for the upper cycle, k_{54} for the lower cycle.

$$k_{21}^1 = \max\{k_{41}k_{32}/k_{21}, k_{52}, k_{63}k_{32}/k_{13}\}, \quad k_{12}^1 = k_{36}k_{54}/k_{46}$$

six possible orderings, each one a different simplification (different acyclic auxiliary dyn. system or different dominant (critical) parameters)

Robustness of linear models

- ▶ Topology is not everything. Order integration ...
- ▶ Slowest relaxation time is an r -th order statistics (under some conditions). Concentration...
- ▶ Kinetic constants of dominated reactions are not critical (only order matters). Max rule...
- ▶ Dimension of dynamics (number of active modes) is low and can change with time and with orders.

variance**

Complex, but not bottom level: the gene circuit model

Model: Hopfield + diffusion

Synthesis

$$\frac{\partial u_a(x,t)}{\partial t} = R_a g_a \left(\sum_{b=1}^N T_{ab} u_b(x,t) + T_{am}(x) + h_a \right)$$

Transport

$$+ D_a \nabla^2 u_a(x,t)$$

Degradation

$$- \lambda_a u_a(x,t)$$

Reproduces canalization properties of the patterns

Gap genes domains are stabilized by gene interactions.

Experimental proof

Manu et al., Plos Biology 09

$$u_t = du_{xx} + R\sigma(Tu + M(x)) - \lambda u$$

kink solution

$$U(x, q) = \frac{R}{\lambda} \times \begin{cases} 1 - \frac{1}{2} \exp(\gamma(x - q)), & x < q, \\ \exp(-\gamma(x - q)), & x > q, \end{cases}$$

Whitham's principle

variational form

$$\frac{\delta D[u_t]}{\delta u_t} = -\frac{\delta F[u]}{\delta u},$$

$D = \frac{1}{2} \int u_t^2 dx$ dissipation functional

$F = \int [\frac{1}{2} du_x^2 + \Phi(u, x)] dx$. energy functional

$\Phi_u = -R\sigma(Tu + M(x)) + \lambda u$ potential

One kink

Potential for a step function

$$\Phi = \begin{cases} RM/T + \lambda u^2/2, & u < -M/T \\ -Ru + \lambda u^2/2, & u > -M/T \end{cases}$$

Whitham averaged functionals

$$\bar{D} = D[U], \quad \bar{F} = F[U].$$

Whitham's principle

$$\frac{d\bar{D}(q_t)}{dq_t} = -\frac{d\bar{F}(q)}{dq}.$$

Model re-writing

$$r \frac{dq}{dt} = \frac{M(q)}{RT} + \frac{1}{2\lambda},$$

where $r = R^{-2} \int_{-\infty}^{\infty} U_x^2 dx = \frac{3}{4} \gamma \lambda^{-2}.$

Several interacting kinks

$$g_i(x, q_1, \dots, q_n) = m_k \mu(x) + h_k + T_{kk} [\tilde{U}_{l(k)}(x) - R_k/\lambda_k] + \\ + \sum_{m \neq k} T_{km} [\tilde{U}_{l(m)}(x) + \tilde{U}_{r(m)}(x) - R_m/\lambda_m],$$

where $\tilde{U}_i = U_i(q_i + s_i(x - q_i))$.

$$r_i \frac{dq_i}{dt} = s_i \left(\frac{g_i}{R_k T_{kk}} + \frac{1}{2\lambda_k} \right).$$

Kink representation of data: robustness of domain positions

$$U(x, q) = \frac{R}{\lambda} \times \begin{cases} 1 - \frac{1}{2} \exp(\gamma(x - q)), & x < q, \\ \exp(-\gamma(x - q)), & x > q, \end{cases}$$

Kink profile

Elastic (springy) morphogenesis

Alternating cushion

$$\frac{dq_i}{dt} = v_i [\alpha_1 e^{-\gamma \delta_i} - \alpha_2 e^{-\gamma \Delta_{i+2}} + \bar{h}_i]$$

$$\frac{dq_{i+1}}{dt} = v_{i+1} [\alpha_2 e^{-\gamma \Delta_i} - \alpha_1 e^{-\gamma \delta_i} - \bar{h}_{i+1}]$$

Interacting kink approximation of GCM

Simplicity of the dynamics

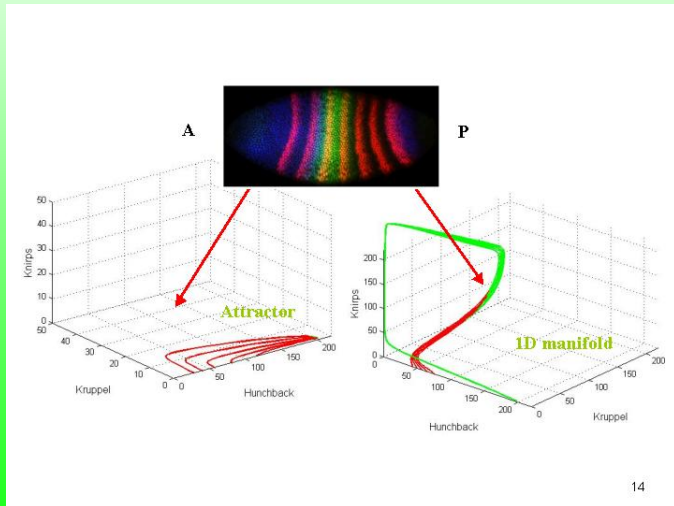

Palis conjecture: every system can be approximated by another having only finitely many attractors.

Simplicity of the dynamics

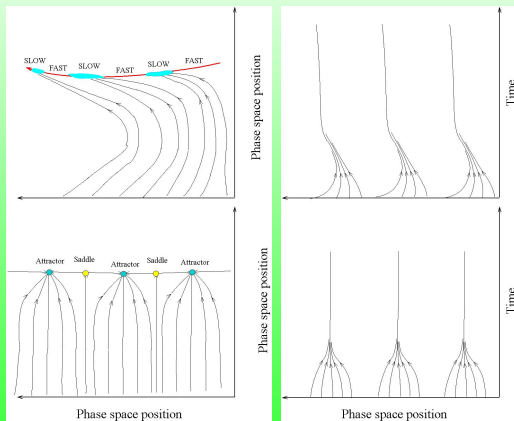

Palis conjecture: every system can be approximated by another having only finitely many attractors.

Diffusionless approximation and canalization

Two canalization schemes

Attractors support SRB (Sinai-Ruelle-Bowen) probability measures. The SRB probability of a state is the inverse of the time spent in the neighborhood of the state.
